This document shall be used and disclosed by the receiving Party and its related entities (e.g. contractors and subcontractors) only for the purposes of fulfilling the receiving Party's responsibilities under the Euclid Project and that identified and marked technical data shall not be disclosed or retransferred to any other entity without prior written permission of the document preparer.

The standard model: cosmic concordance, but many open questions...

Amanullah et al. 2010 (Union supernovae)

1. Is cosmic acceleration produced by a cosmological constant or by an evolving scalar field?

Parameterizing our ignorance

e.g. $w(a) = w_0 + w_a(1 - a)$

It has become customary to characterize future surveys through a Figure of Merit in this or similar plane:

$$\text{FoM} = 1/(\Delta w_0 \times \Delta w_a)$$

But this reflects chosen parameterization

→ FoMs should be taken with grain of salt (e.g. NASA/DOE/ESA FoMSWG report, Albrecht et al. 2009)

Wood-Vasey et al. 2007

A story with two sides...

$$\left(R_{\mu\nu} - \frac{1}{2} g_{\mu\nu} R \right) = -\frac{8\pi G}{c^2} T_{\mu\nu} + \Lambda g_{\mu\nu}$$

Modify gravity theory [e.g. $R \rightarrow f(R)$]

Add dark energy

→ Distinguish by measuring both background expansion $H(z)$ and growth rate of structure $f(z)$

1. Is cosmic acceleration produced by a cosmological constant or by an evolving scalar field?
2. Does General Relativity need to be modified on cosmological scales?

1. Measure expansion history $H(z)$ to high accuracy, as to detect percent variations of DE *equation of state* $w(z)$ with robust control of systematics.

Achieve this through **two probes**:

- A. **Measurement of geometry through Weak Gravitational Lensing**
- B. **Baryonic Acoustic Oscillations (BAO) in the clustering pattern of galaxies as standard rod**

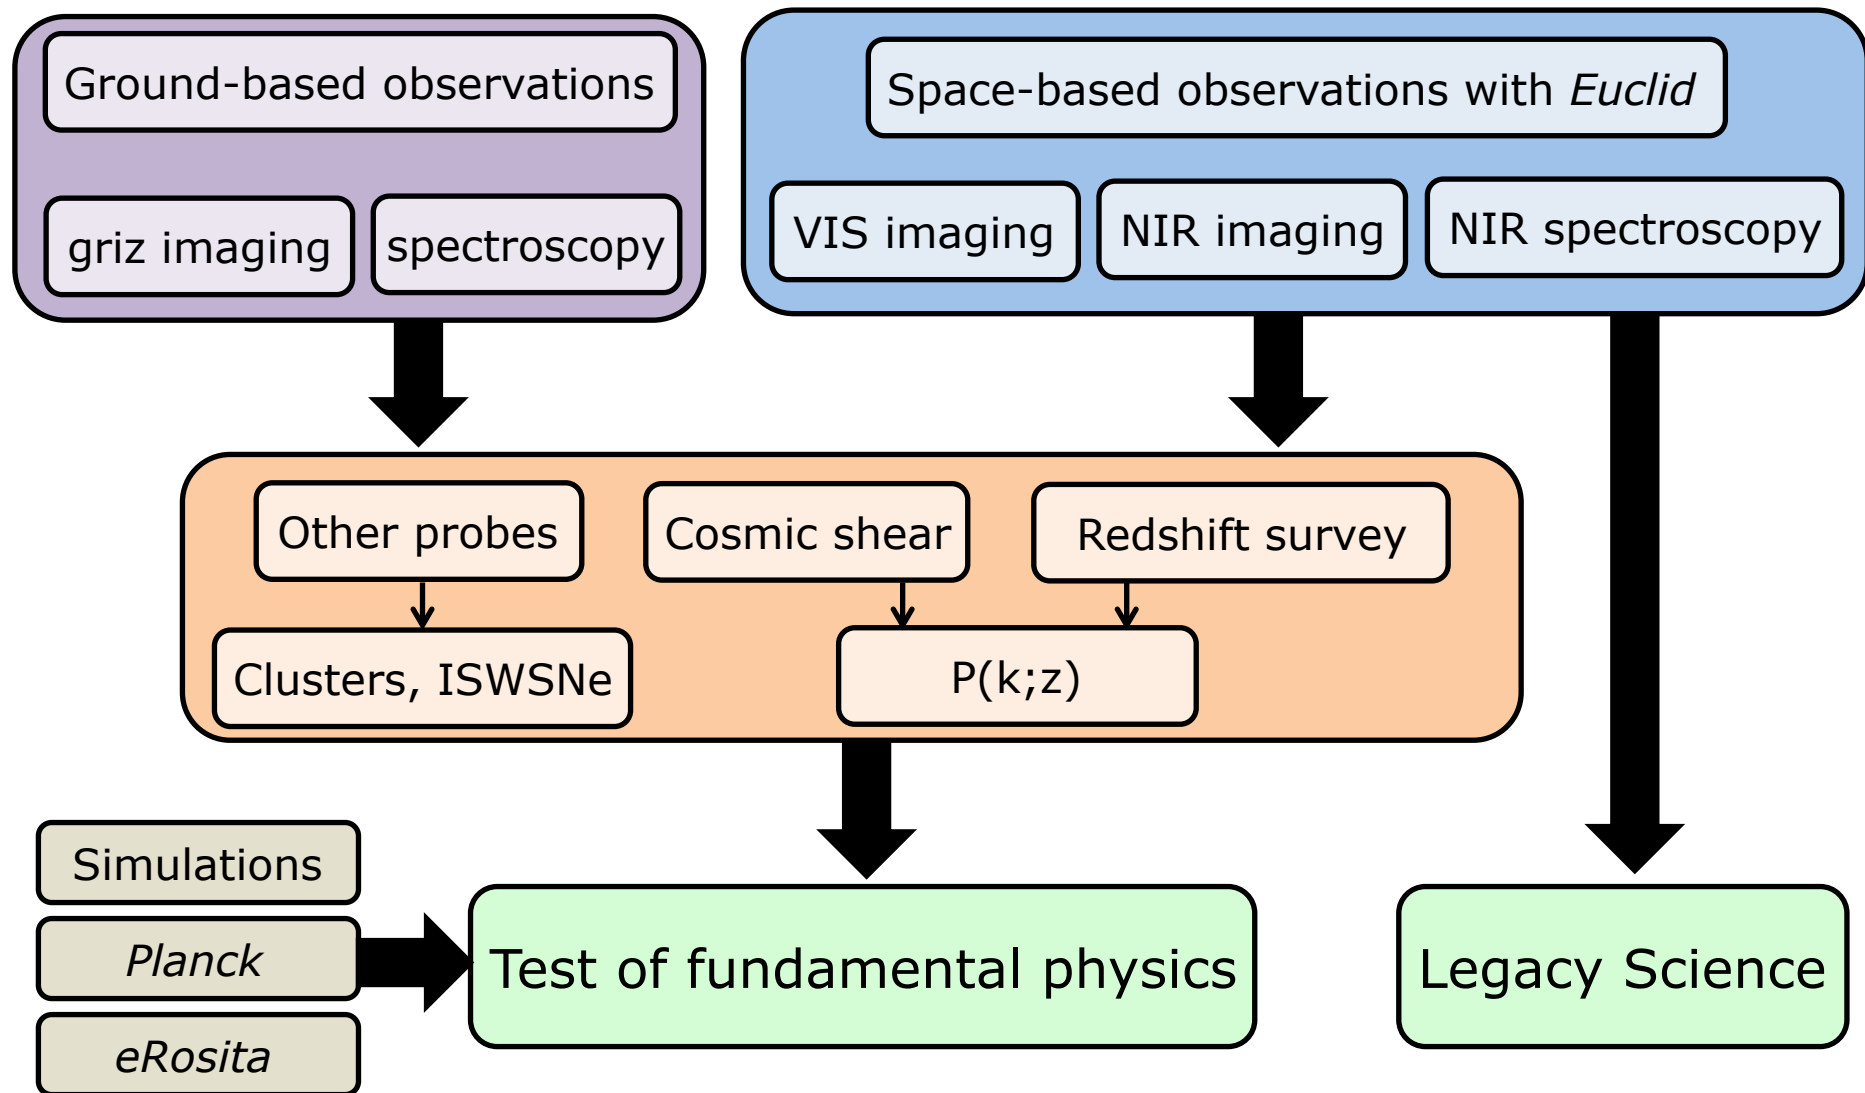

1. Measure expansion history $H(z)$ to high accuracy, as to detect percent variations of DE *equation of state* $w(z)$ with robust control of systematics.
2. Measure at the same time growth rate of structure from the same probes:
 - A. Weak Lensing Tomography
 - B. Redshift-space distortion of clustering (RSD)

How to do this with Euclid

Euclid
Consortium

Density fluctuations in the universe affect the propagation of light rays, leading to correlations in their *observable* shapes.

The statistics of shape correlations as a function of angular scale and redshift can be used to *directly* infer the statistics of the density fluctuations and consequently cosmology.

- Measures a combination of geometry (thus $H(z)$) and growth
- To achieve the science goals we need to measure the matter distribution as a function of redshift: weak lensing tomography requires redshifts for the sources.

Probe 2: Galaxy Clustering

Euclid
Consortium

Baryonic Acoustic Oscillations

Euclid
Consortium

Galaxies

Percival et al. (2007, 2009, 2010); Anderson et al 2012

Microwave background

WMAP, e.g. Komatsu et al. 2009

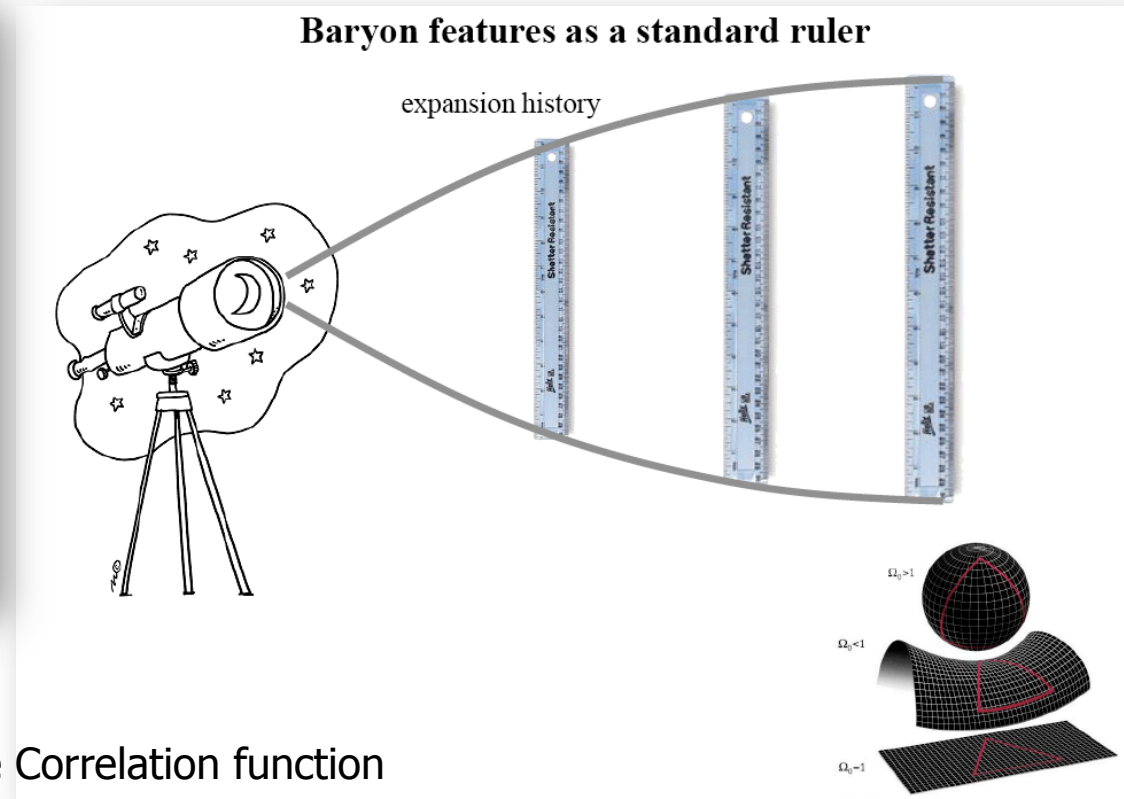

- Measure $H(z)$ from redshift surveys

SDSS: Eisenstein et al 2005

BAO: a broad feature in the Correlation function

w(z) from Baryonic Acoustic Oscillations

Euclid
Consortium

SDSS LRGs at $z \sim 0.35$

Total effective volume
 $V_{\text{eff}} = 0.26 \text{ Gpc}^3 h^{-3}$

20% of the Euclid slitless data at $z \sim 1$

Total effective volume (of Euclid)
 $V_{\text{eff}} = 19.7 \text{ Gpc}^3 h^{-3}$

1. Dark Energy equation of state from combined Weak Lensing and Galaxy Clustering (BAO)

Answering Euclid key science question 1: Is dark energy simply a cosmological constant, or is it a field that evolves dynamically with the expansion of the Universe?

Growth rate of structure depends on gravity theory

Growth produces motions: galaxy peculiar velocities

Figure by K. Dolag 8

In galaxy redshift surveys peculiar velocities manifest themselves as redshift-space distortions (Kaiser 1987)

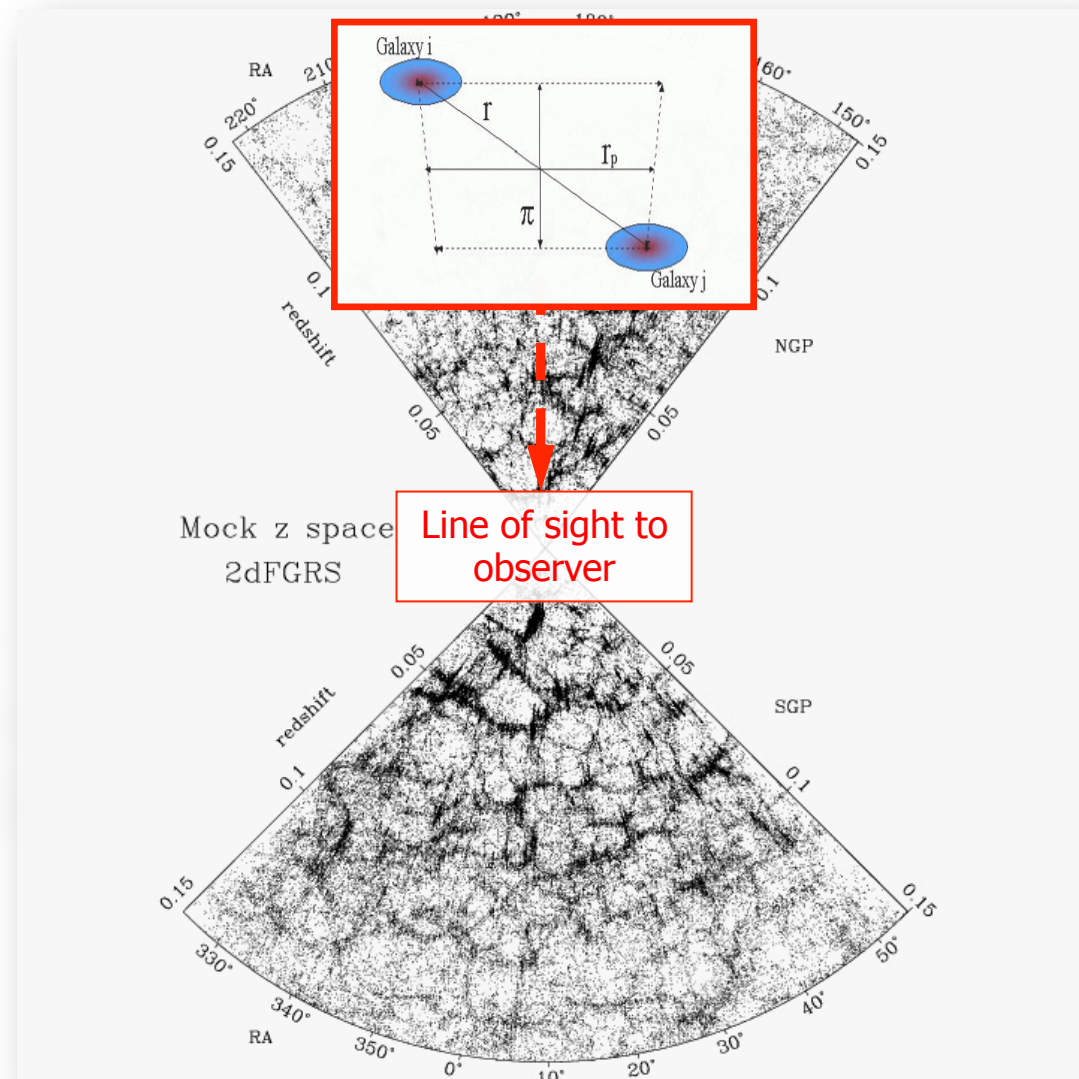

real space

In galaxy redshift surveys peculiar velocities manifest themselves as redshift-space distortions (Kaiser 1987)

Guzzo et al., Nature 451, 541 (2008)

- Redshift-space distortions map motions due to structure growth

$$\sigma_z = 0.001(1+z)$$

$$\sigma_z = 0.0$$

EUCLID lightcone (100deg²)
 $S_{H\alpha} < 1 \times 10^{-16} \text{ erg/s/cm}^2$

sims by Bianchi et al. (2011)

(sims from Durham group)

2. Growth rate of structure from combined Weak Lensing (tomography) and Galaxy Clustering (redshift-space distortions)

$$f(z)=[\Omega_m(z)]^\gamma$$

$$P_o(k)=Ak^n$$

Answering Euclid key science question 2: Is the apparent acceleration instead a manifestation of a breakdown of General Relativity on the largest scales?

LINKS TO GROUND-BASED SPECTROSCOPY

- Required to reach dark energy and modified gravity objectives
- Accurate Shape Measurement
 - Achieved through stable satellite and space environment
 - Small diffraction limited PSF
 - Resolved galaxies (small pixels $0.1''$)
 - Broad optical filter RIZ to achieve required S/N
- Redshift Estimate
 - Necessarily photometric redshifts (too many for spec-z)

- The lensing kernel is most sensitive to structure halfway between the observer and the source. But the kernel is broad: we do not need precise redshifts for the sources: **photometric redshifts are fine**
- Also, since the kernel is broad the tomographic bins are very correlated. The gain saturates quickly with the number of bins: **not many z bins**

Geometry Large Scale Structure

$$C_{ij}(\ell) = \int_0^{r_H} dr W_{ij}^{GG}(r) P_{\delta\delta}\left(\frac{\ell}{S_k(r)}; r\right)$$

Lensing Power Spectrum

- 1) On board NIR bands (JHK)
- 2) Ground-based optical photometry (griz)

- Optical griz+Euclid(YJH) meets requirements on photo-z errors

Abdalla et al. (2007)

(T. Kitching, H. Hoekstra, B. Joachimi, et al.)

Gravitational lensing is not the only source of shape alignments. The local gravitational tidal field generates torques and shear forces.

- Shapes and angular momenta of galaxies are intrinsically aligned
- Leads to additional contributions to the ellipticity correlation function:

$$\epsilon_{\text{observed}} = \gamma + \epsilon_{\text{intrinsic}} + \text{noise}$$

$$\langle \epsilon_i \epsilon_j \rangle = \underbrace{\langle \gamma_i \gamma_j \rangle}_{\text{GG}} + \underbrace{\langle \epsilon_i^s \epsilon_j^s \rangle}_{\text{II}} + \underbrace{\langle \gamma_i \epsilon_j^s \rangle + \langle \epsilon_i^s \gamma_j \rangle}_{\text{GI}}$$

We currently know little about intrinsic alignments. We therefore have to model the signal using a generic (flexible) approach. This leads to a preference of a deeper, but smaller survey for a given survey duration.

The intrinsic alignments signal can be measured by correlating the shapes of galaxies that are physically associated, i.e. close in redshift. The required ground-based imaging data allow us to do this: Euclid survey “sweet spot” at 15,000 deg²

The few observational constraints (supported by results from numerical simulations) suggest that early type galaxies may show stronger alignments. As they tend to be associated with more massive structures, they also contribute most to the GL signal.

A spectroscopic survey of early type galaxies would be extremely useful to improve the measurement of the IA signal, and thus improve the precision of the cosmic shear results.

- R-WL.1-7: The mean of the redshift distribution $n(z)$ in each tomographic redshift bin shall be known to a precision of $\sigma(\langle z \rangle)/(1+z) < 0.002$
- R-EXT.2-1: Spectroscopic redshifts for more than 10^5 galaxies shall be available. The properties of these galaxies should be representative of the full population of galaxies used in the weak lensing analysis. The fraction of galaxies for which redshifts could not be determined should be $< 4 \times 10^{-4}$.

The completeness needs to be confirmed.

So, Euclid WL does need ground-based redshifts ...

What is / will be available?

ESO PR, Le Fèvre et al 2006

- **CFHTLS : VVDS** with VMOS,
 - 32,000 redshifts to $I=22.5$ over $\sim 15 \text{ deg}^2$, (Garilli et al 2008)
 - 15,000 to $I=24$ over $\sim 1 \text{ deg}^2$ (Le Fèvre et al 2005)
 - 1000 redshifts $23 < I < 24.75$ over 0.15 deg^2 (Le Fèvre et al 2012)
- **CFHTLS : VIPERS** with VMOS:
 $\sim 100,000$ redshifts to $I=22.5$ over 25 deg^2 (Guzzo et al 2012)
- **COSMOS : z-Cosmos** with VMOS:
 - $\sim 20,000$ redshifts to $I=22.5$ over 1.7 deg^2 (Lilly et al 2009)
 - $\sim 10,000$ redshifts $B < 25.25$ color selected, over 0.9 deg^2

... How can we get 10^5 redshifts for $I=24.5$ + subsamples to $I > 24.5$??

- Need angular galaxy positions
- Need galaxy redshifts

- Need to understand population
 - angular completeness
 - radial completeness
 - radial/angular fluctuations

This is the
hard part

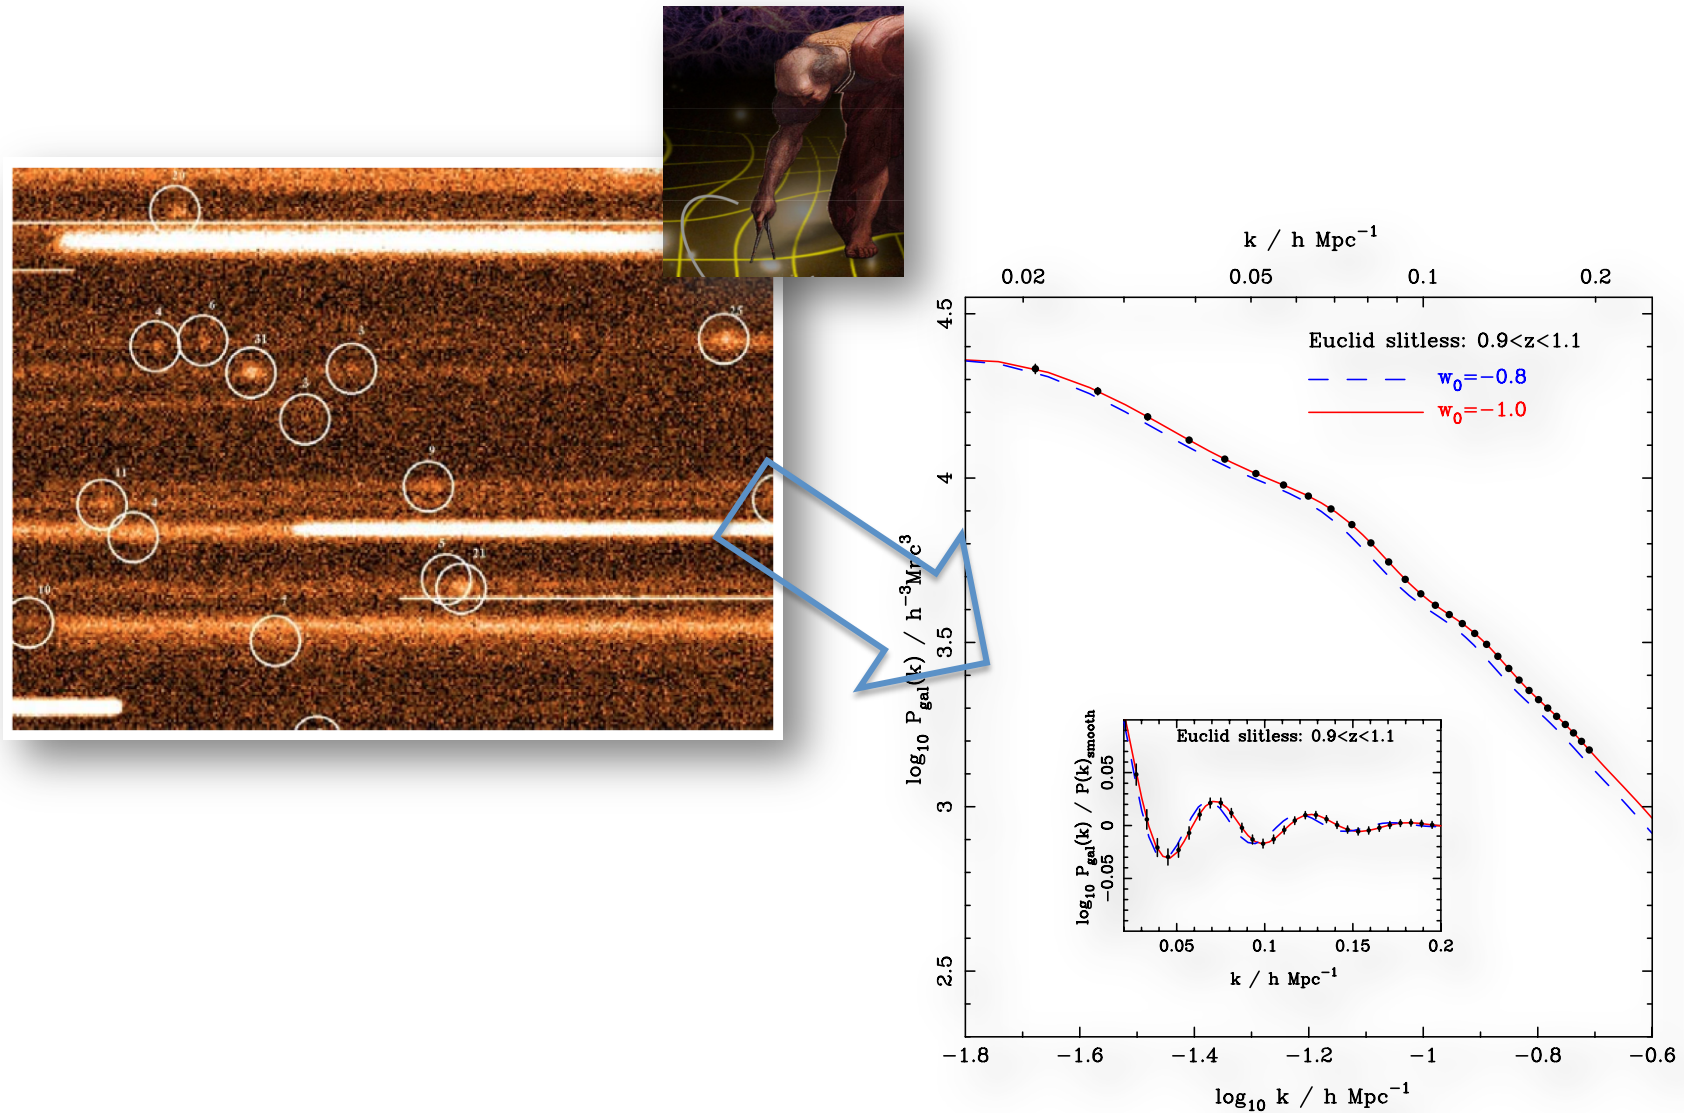

- Then we can go from a density field to an overdensity field, and measure statistically the amplitude and anisotropy of clustering (correlation function, power spectrum)

- Near-IR spectroscopy targets rest-frame optical for $z > 0.7$: best complementary with low- z ground-based optical (e.g. SDSS)
- Very high-multiplexing NIR spectroscopy not feasible from the ground: sky-line forest needs higher dispersion (long spectra, low packing)
- H-alpha is a primary tracer of the star formation rate: abundant at early epochs \rightarrow enough galaxy density at high redshift to achieve cosmology statistical goals
- The most important emission lines are in the rest-frame optical (i.e. redshifted in the near-IR for $z > 0.7$)
- H-alpha is less affected by galaxy internal dust extinction than other lines in the blue (e.g. a factor of about 2 less than [OII]3727)
- Slitless technique provides an *a priori* uniform sample, with no need to specify a target sample
- There is no free lunch, however. Simpler to do, more complex to understand

The long way from raw data to cosmology

Euclid
Consortium

Slitless spectroscopy is technically simpler, but the resulting selection function is complex: confusion of adjacent spectra makes measuring redshifts more difficult in crowded areas:

- **Completeness:** what fraction of all galaxies expected to a given limit (in $H\alpha$ flux) will not have a redshift because of confusion?
- **Purity:** what fraction of the measured redshifts is correct (within statistical errors) i.e. how many catastrophic errors do we expect? And which is their redshift distribution?

The main problem is that for these observations there is no such a thing as a **parent sample**: we know the flux of our objects only *after* performing the spectroscopic observations (no “a priori” mag-limited sample, as in standard slit-based redshift surveys)

- Well understood sample of galaxies ($0.7 < z < 2.0$) with accurate redshifts $\sigma_z < 0.001(1+z)$
- We want:
 - High and controlled redshift measurement success rate:
 - Angular position (density dependence \rightarrow control spectral confusion)
 - Redshift (wavelength dependence \rightarrow control flux limit)
 - Control catastrophic redshifts ($< 20\%$ from L1):
 - Accurately know their fraction (error $< 1\%$)
 - Accurately know mean in redshift shell (systematic \ll statistical)
- **Need control sample of $\sim 2 \times 10^5$ redshifts, with purity $> 99\%$ at the depth of the Euclid survey: Deep Field**
- Shall we need a ground-based spectroscopic follow-up of the Deep field?
- This is not a requirement, but might be desirable at some point, given the accuracies we are aiming at...

GENERAL:

1. Euclid will perform an unprecedented redshift survey of the $0.7 < z < 2.1$ Universe, building a sample of $\sim 6 \times 10^8$ galaxies with measured distances (and much more)
2. Results combined with WL companion survey may well revolutionize our understanding of physics

GALAXY CLUSTERING PROBE:

1. Slitless spectroscopy targeting H-alpha: simpler to do for the engineers, complex to understand for astronomers, limited spectral information for legacy
2. Simulations fundamental to understand systematics
3. Deep calibration field will provide the crucial “real thing” to believe the simulations and provide final calibration
4. Any follow-up spectroscopy may clean important aspect and lead to “gold” samples to verify broader cosmological results: worth having, given the potential of the Euclid data
5. Of course, spectroscopic follow-up of specific objects will be interesting per se from the galaxy evolution point of view

WEAK LENSING:

1. Euclid will perform an unprecedented imaging survey of $\sim 10^9$ galaxies with measured shapes
2. Support ground-based spectroscopy is an important part of the photometric-redshift calibration
3. Also crucial to disentangle intrinsic alignments
4. Spectroscopy of $\sim 10^5$ galaxies at $z \sim 1-3$ down to $I \sim 24.5$ needed, with proper coverage of SED types

To date the Euclid Consortium (EC) includes members from 14 European countries (Austria, Belgium, Denmark, Finland, France, Germany, Italy, the Netherlands, Norway, Portugal, Romania, Spain, Switzerland and the United Kingdom), with additional contributions from a few US laboratories.

In total, nearly 1000 scientists are registered in the EC, which makes it the largest astronomy consortium to date. More than 100 European laboratories covering all fields in cosmology, theoretical physics, high energy, particle physics and space science contribute to Euclid.
